Instructions:

To ensure that the driftwood sinks deeper into the aquarium, it should be pre-treated before being placed in the water:

1. Start by soaking the driftwood in water with soda and salt, then bring it to a boil. Boil for at least 1 hour, and you'll notice the tannins being released and the color darkening.
2. Change the water and boil it again. Boiling the water 3-5 times is recommended, then soaking the driftwood in water. When soaking driftwood in water, change the water once a day. In general, the tannins can be removed entirely within a week.

If you find boiling and soaking very time-consuming, you may purchase protein cotton for your aquarium filter. Place the protein cotton into the filter bucket. Turn on the filter to start the filtration cycle so that the tannins released by the wood are quickly absorbed, and the aquarium water does not turn yellow.
